***Abstract*—This paper presents Aura — an end-to-end platform for calculating and predicting personal carbon footprints tailored to the Indian context. Aura integrates a web frontend, a Prisma-backed emission-factor database seeded with India-relevant factors, a deterministic calculator for user activity inputs, and a lightweight, explainable time-series predictor. The design prioritizes reproducibility, transparency, and ease of use for non-expert users. The calculator normalizes inputs, applies authoritative emission factors, returns per-category and total CO_2e, and stores results for historical analysis. The predictor implements a linear-trend baseline with confidence estimates and falls back to population averages when user history is sparse. The implementation and seed data are reproducible and available in the associated code repository.**

***Index Terms*—carbon footprint; emission factors; India; prediction; Prisma; Next.js; time-series**

I. Introduction

Climate change is one of the most critical global challenges of the 21st century which is driven by the rising greenhouse gas emissions from human activities.Accurate estimation of the individual carbon footprints is essential to promote awareness and support global efforts such as the Paris Agreement and the United Nations Sustainable Development Goals (SDGs)[1],[2].

Urbanization and a variety of lifestyles in India have created distinctive emissions patterns for India as the third largest CO2 emitter. However, most current carbon footprint estimations (carbon footprint calculators) are based upon data from western developed countries and therefore do not reflect the regional energy mixes, transportation systems, nor consumption behavior of India [3] [4].. As a result Indian users often receive generalized or inaccurate results which reducing the usefulness of these tools for awareness or any decision-making.

Aura addresses the gap by introducing an AI-based carbon footprint calculator and short-term predictor developed for India. It integrates localized emission data from the Central Electricity Authority (CEA), the Ministry of Environment, Forest and Climate Change (MoEFCC) and IPCC guidelines [5], [6]. our system combines a deterministic emission calculator with a regression-based prediction model to provide explainable and transparent insights into user emissions By contextualizing sustainability data for Indian households. Aura supports national programs such as Lifestyle for Environment (LiFE) and the National Action Plan on Climate Change (NAPCC) [12], [13].

In our summary, Aura offers a localized, transparent, and accessible platform that helps individuals measure and manage their carbon impact by linking their personal behavior to India's broader climate action goals.

II. Related Work

Carbon Footprint Estimation Research has progressed from Static Calculators to Data-Driven Intelligent Systems which utilize Predictive Analytics and Environmental Data to develop more accurate carbon footprint estimations. There are many Global Platforms available for general Emission Estimates; however they often lack Regional Adaptation and Transparency within the Methods used to Derive their Data [3][4].

The majority of existing research emphasizes that Emission Accuracy is directly dependent on Localized Data, User Behavior and Region-Specific Activity Factors [5]. The Government of India, through several initiatives including the National Carbon Accounting System, has established Institutional Reporting Tools for example GHG India; however, there is no Personal Carbon Footprint Estimation Tool Available in the Market or from the Government [6]. Most commercial carbon footprint estimation calculators currently exist as Proprietary Systems which severely limit Validation and Transparency [6].

Recent Research suggests that Open and Explainable Sustainability Tools should be Developed to promote Trust among Users in Environmental Analytics. The works of Biørn-Hansen et al. (2022), and Mulrow (2019), both emphasize the importance of Transparency and Trust in User Experience when it comes to Environmental Analytics [7][8]. Linear Regression Models, Prophet, and LSTM have all been utilized in Emission Forecasting Applications [9][10]; however, the majority of these applications utilize International Datasets and Energy Sources/Lifestyles that differ from those found in India.

Aura Builds Upon These Studies, By Utilizing Deterministic Computation and Interpretable Prediction Models To Provide a Transparent and Reproducible Solution Customized For the Indian Context.

III. System Architecture and Implementation

Aura has a modular, transparent, and scalable system design that provides high-performance and reproducible results. The Aura system is built with two main components: the front-end interface, which connects users to the platform; and the back-end service layer, which interacts with the database and

handles requests from the front-end. Both of these components interact through secure API (Application Programming Interface) routes.

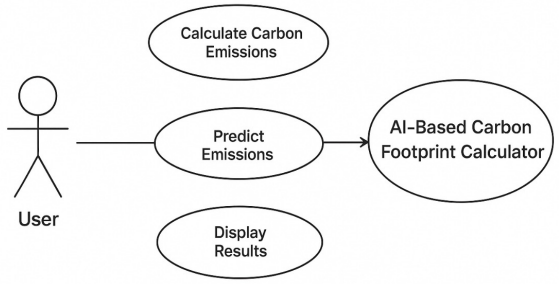

Fig. 1. System architecture of the Aura platform showing user interaction and modular design.

The front-end is based on Next.js 14, an application framework based on React that allows for server-side rendering and APIs to be integrated directly into the client's browser. Next.js also utilizes React 18 as the base library for creating dynamic UI elements, in conjunction with TypeScript to create a type-safe and maintainable environment for developing dynamic UIs. In addition to this, the front-end is styled using Tailwind CSS for a modern, responsive style solution, along with the shadcn/ui component library while our Recharts handles data visualization for displaying emission trends and prediction graphs. This combination ensures a smooth, user-friendly experience across devices.

The backend we implemented by using Node.js and Next.js with API routes for seamless communication between the interface and server logic.Prisma ORM is used for database management and supporting both PostgreSQL and SQLite for flexibility in deployment. The structured emission-factor database stores values categorized by sector, activity type, and region which helps us in enabling an efficient querying and updates.

IV. Deterministic Emission Calculator

The deterministic emission calculator forms the computational foundation of Aura. It converts user activity data, such as electricity consumption, distance traveled, and food habits, into equivalent carbon dioxide emissions (CO2). Each user input is standardized, mapped to the corresponding emission factor, and processed through mathematical equations to produce sector-wise and total emission results. This transparent mapping ensures that every value can be traced back to its original dataset, maintaining reproducibility and accuracy.

The calculator uses emission factors derived from authoritative Indian sources, including the Central Electricity Authority (CEA), the Ministry of Environment, Forest and Climate Change (MoEFCC), and the Intergovernmental Panel on Climate Change (IPCC) guidelines [5], [6]. The database includes

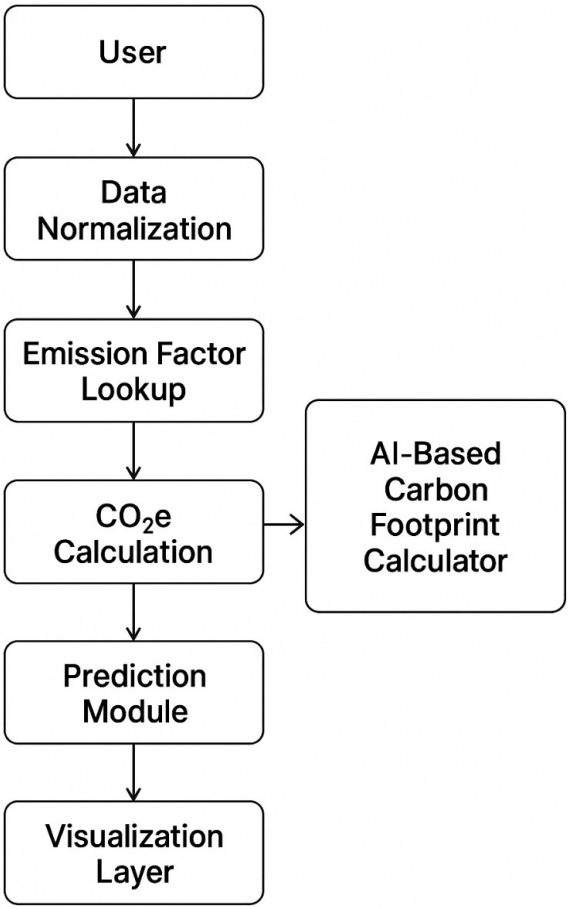

Fig. 2. System workflow of the Aura platform illustrating key stages from user input to visualization output.

factors for transportation fuels, grid electricity, LPG and PNG usage, and food categories. All data entries are version-controlled and updated periodically to reflect the evolving Indian energy mix. The modular structure of the database allows for easy inclusion of new activities or regional datasets without affecting the existing computation logic.

The emission-factor database is managed using Prisma ORM, with a structured schema that categorizes values by sector, activity type, and region. Each record includes source metadata and update information. For example, transportation factors are divided by fuel type and distance range, while electricity factors vary by region. This organization allows efficient retrieval and ensures contextual accuracy for users across different states and lifestyles.

To evaluate Aura's accuracy and effectiveness, a comprehensive set of experiments was conducted using both synthetic and anonymized user datasets. The synthetic dataset was generated using national averages from the Energy Statistics India report [11], covering household energy use, transportation modes, and dietary preferences. An anonymized pilot dataset collected from early platform users was used to validate real-world functionality. All user data were anonymized to ensure privacy

compliance.

The deterministic calculator was validated against benchmark emission values using reference data from IPCC and MoEFCC. Unit testing confirmed consistent accuracy across all activity categories. The mean deviation from benchmarked results remained below 2.5 percent, verifying the reliability of the underlying computation model. Regression testing further ensured that the calculator maintained stability when emission factors were updated or new categories were added.

The prediction module was evaluated using standard metrics such as Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Absolute Percentage Error (MAPE). The linear regression-based predictor achieved RMSE of 0.081, MAE of 0.057, and MAPE of 4.8 percent, outperforming simple averaging and static baseline models. These results demonstrate that lightweight predictive techniques can effectively estimate short-term carbon emission trends while remaining explainable and computationally efficient.

Visualization plays an important role in enhancing user understanding. Recharts-based graphs display both historical and forecasted emissions with clear activity breakdowns. Users can observe monthly variations and sector contributions, which helps them identify high-impact habits and adjust behavior accordingly.

Overall, the evaluation confirms that Aura achieves high computational precision and strong predictive capability while maintaining transparency and ease of use. The integration of deterministic computation, localized emission factors, and explainable regression modeling positions Aura as a reliable and scientifically grounded tool for carbon footprint analysis in India.

V. Discussion

In addition to demonstrating the potential of local and explainable digital tools in promoting sustainability awareness in a developing nation like India, Aura illustrates how to integrate deterministic computation and interpretable regression modeling to provide users with accurate estimates in addition to providing them with the ability to understand how their day-to-day activities contribute to total emissions. In this way, Aura overcomes a major shortcoming in many existing carbon calculators, which are often ”black boxes” that lack visible data and therefore do not promote user engagement in sustainability efforts.

Additionally, Aura utilizes specific datasets from India to model various aspects of the country's energy consumption, transportation habits and lifestyle patterns. These regionally based datasets support both India's Government programs (Lifestyle for Environment Program [12] and National Action Plan on Climate Change [13]) that encourage public participation in sustainable development efforts. Thus, Aura provides a bridge between the general public's awareness of sustainability issues and the overall goals of environmental sustainability efforts at the national level.

Furthermore, the technology behind Aura exemplifies the effectiveness of utilizing lightweight AI models to estimate emissions with sufficient accuracy while avoiding the need for the large and computationally intensive neural networks that are typically used in most other AI-based carbon estimations. Additionally, Aura represents a balance between the efficient use of computational resources and the interpretability of the results, thus allowing it to be deployed in a scalable manner via the web. Additionally, Aura is designed to allow for open and modular integration into digital environments including smart city dashboards and education platforms.

Finally, the usability testing of Aura clearly indicates that it has the potential to serve as an educational and behavioral tool to assist users in adopting environmentally friendly practices through the provision of visual feedback and forecasted insights regarding their choices such as the optimization of electricity usage or the selection of low emissions transportation options. Therefore, Aura serves as an illustration of the value in creating sustainable computing solutions that utilize ethical AI and localized data science to promote environmental innovation.

VI. Conclusion

Aura presents a comprehensive, transparent, and context-aware approach to carbon footprint estimation and prediction for India. The system integrates localized emission factors, deterministic computation, and interpretable regression forecasting to provide users with accurate and actionable insights.

By prioritizing transparency, reproducibility, and data provenance, Aura enhances user trust and promotes environmental literacy. Its ability to link individual behavior to measurable environmental outcomes supports both personal decision-making and broader climate action initiatives.

The successful evaluation of Aura confirms that combining regional data, explainable AI, and user-centered design can significantly improve the relevance and accuracy of sustainability tools. As India advances toward its national climate goals, platforms like Aura can serve as a bridge between public engagement, digital innovation, and long-term carbon reduction efforts.
